Exploratory Data Analysis (EDA)

1. Introduction

Exploratory Data Analysis (EDA) is the process of scrutinizing datasets to summarize their fundamental characteristics, often utilizing statistical graphics and other visualization methods. The aim of EDA is to uncover patterns within the data to derive meaningful insights. To achieve this objective, exploration is conducted on a particular dataset to identify, understand, and categorize its features.

For instance, let's consider the Pima Indians diabetes dataset. In the subsequent sections, we will delve into the exploration process as outlined.

1.1 Getting the data.

The dataset is readily available in the UCI repository and can be downloaded from the following;

URL. https://www.kaggle.com/datasets/uciml/pima-indians-diabetes-database/

1.1.1 Dataset Context

The source of this dataset is the National Institute of Diabetes and Digestive and Kidney Diseases. The dataset goal is to predict, diagnostically, whether a patient has diabetes or not, utilizing specific diagnostic measurements provided within it. Certain criteria were applied when selecting these instances from a larger database. Specifically, all the patients included in this dataset are females of at least 21 years of age, and they belong to the Pima Indian heritage.

1.1.2 Dataset Data dictionary:

Below is the attribute information:

- Pregnancies: Number of times pregnant
- Glucose: Plasma glucose concentration a 2 hours in an oral glucose tolerance test
- Blood pressure: Diastolic blood pressure (mm Hg)
- SkinThickness: Triceps skinfold thickness (mm)
- Insulin 2-Hour serum insulin (mu U/ml) test
- BMI: Body mass index (weight in kg/(height in m)^2)

- DiabetesPedigreeFunction: A function that scores the likelihood of diabetes based on family
- history
- Age: Age in years
- Outcome: Class variable (0: the person is not diabetic or 1: the person is diabetic)

Now that we have gained some insight into our dataset and the objective of our analysis (which is to explore the patterns and trends of diabetes within the Pima Indians population), let's delve directly into the analysis 1.2 Objective

The first and foremost important thing in EDA is setting a goal. Our goal is to draw meaningful inferences which in turn will be used in identifying diabetes in a person.

2. Implementation

To achieve the stated objective, we need well set environment for data analysis. In this case, we shall use ANACONDA platform. Using Jupyter.

2.1 Reading Data

Import all the related libraries

```
##Loading libraries
import pandas as pd
import numpy as np
import seaborn as sns
import matplotlib.pyplot as plt

Python libraries

importing file

df=pd.read_csv("diabetes.csv")

Csv file
```

We assign our dataset as df

2.2 Understanding the data

Taking time to go through the data to understand its characteristics and gather information on general knowledge with in regard to the field that re very important during the analysis. 2.2.1 Reviewing the data frame info

```
df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 768 entries, 0 to 767
Data columns (total 9 columns):
   Column
                              Non-Null Count Dtype
0
    Pregnancies
                              768 non-null
                                             int64
1
    Glucose
                              768 non-null
                                             int64
2
    BloodPressure
                              768 non-null
                                             int64
3
    SkinThickness
                              768 non-null
                                             int64
4
    Insulin
                              768 non-null
                                             int64
5
    BMI
                                             float64
                              768 non-null
    DiabetesPedigreeFunction 768 non-null
                                             float64
6
7
                              768 non-null
                                           int64
    Outcome
                              768 non-null
                                             int64
dtypes: float64(2), int64(7)
memory usage: 54.1 KB
```

This gives information on dataset variables, their data types, helps us Identify if there are missing values. We can also tell if the variables are assigned the right data types. In this case, the data types are assigned correctly and there are no nonvalues.

This outputs all the variables or features in our df

df.head()

2.2.2. View 5 records to better understand the data

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	ВМІ	DiabetesPedigreeFunction	Age	Outcome
0	6	148	72	35	0	33.6	0.627	50	1
1	1.	85	66	29	0	26.6	0.351	31	0
2	8	183	64	0	0	23.3	0.672	32	1
3	1	89	66	23	94	28.1	0.167	21	0
4	0	137	40	35	168	43.1	2.288	33	1

Returns the first five rows of the dataset. We can also see that all the data is numerical with our target variable being categorical with a numerical attributes of 0 and 1.

From the table, we can point out zero attributes. This variables cannot be zero in the real world. From the table,

Insulin has zero in rows 1, 2, 3, SkinThickness in row 3. In this case we take the values as outliers which ought to be dropped when cleaning the data.

2.2.3. Describe various properties of the data

In this section we produce the descriptive statistics.

```
df.describe()
```

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	BMI	DiabetesPedigreeFunction	Age	Outcome
count	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000	768.000000
mean	3.845052	120.894531	69.105469	20.536458	79.799479	31.992578	0.471876	33.240885	0.348958
std	3.369578	31.972618	19.355807	15.952218	115.244002	7.884160	0.331329	11.760232	0.476951
min	0.000000	0.000000	0.000000	0.000000	0.000000	0.000000	0.078000	21.000000	0.000000
25%	1.000000	99.000000	62.000000	0.000000	0.000000	27.300000	0.243750	24.000000	0.000000
50%	3.000000	117.000000	72.000000	23.000000	30.500000	32.000000	0.372500	29.000000	0.000000
75%	6.000000	140.250000	80.000000	32,000000	127.250000	36.600000	0.626250	41.000000	1.000000
max	17.000000	199.000000	122.000000	99.000000	846.000000	67.100000	2.420000	81.000000	1.000000

We get descriptive statistics for all the variables which are all numerical.

2.2.4. Understanding the outcomes Outcome is our target variable.

```
df["Outcome"].unique()
array([1, 0], dtype=int64)
```

This indicates that there are 0 and 1

Attributes for outcome. 0 for non-diabetic and 1 for diabetic

```
df["Outcome"].value_counts()

Outcome
0 500
1 268
Name: count, dtype: int64
```

This shows that there are 268 people having

Diabetes and 500 who don't have the disease.

2.2.5. To check if there are any null values in the data set

```
df.isnull().sum()
Pregnancies
Glucose
BloodPressure
                             0
SkinThickness
                             0
Insulin
                             0
BMI
                             0
DiabetesPedigreeFunction
Age
Outcome
                             0
dtype: int64
```

The zeros from this table indicates that there are no missing values. If

there were non-values we would have imputed them with mean/ median and just drop them.

2.3 Cleansing the Data

Errors can evolve from duplicated data, missing values, incorrect attributes, inconsistency and irrelevant data or outliers.

We have already observed outliers. 2.3.1.

Filtering Non-zero records

We previously observed zeros in variables that can never be zero. We take them as outliers.

We drop all the records from the data frame where either Insulin or Blood Pressure or Skin Thickness or BMI, or Glucose levels are 0, through the following codes

```
df[df['Insulin']!=0]
df[df['Glucose']!=0]
df[df['BloodPressure']!=0]
df[df['SkinThickness']!=0]
df[df['BMI']!=0]
```

2.3.2. Confirming that Zero-valued records are deleted

We run the following commands to see if the above rows have been deleted from the data.

```
df.shape
(392, 9)
```

Initially the rows were 768 and now they are 329. The columns

remains

Constant.

This is another proof that the records were dropped

df.describe()							
ssure SkinThio	ckness Insulin	вмі	DiabetesPedigreeFunction	Age	Outcome		
00000 392.0	000000 392,000000	392.000000	392.000000	392.000000	392,000000		
3265 29.1	145408 156.056122	33.086224	0.523046	30.864796	0.331633		
06092 10.5	516424 1 <mark>1</mark> 8.841690	7.027659	0.345488	10.200777	0.471401		
00000 7.0	000000 14.000000	18.200000	0.085000	21.000000	0.000000		
00000 21.0	000000 76.750000	28,400000	0.269750	23,000000	0.000000		
00000 29.0	000000 125.500000	33.200000	0.449500	27.000000	0.000000		
00000 37.0	000000 190.000000	37.100000	0.687000	36.000000	1,000000		
00000 63.0	000000 846.000000	67.100000	2.420000	81.000000	1.000000		
)	0000 63.	0000 63.000000 846.000000	0000 63.000000 846.000000 67.100000	0000 63.000000 846.000000 67.100000 2.420000	0000 63.000000 846.000000 67.100000 2.420000 81.000000		

We no longer have 0 as the minimum values for Glucose BloodPressure SkinThickness Insulin BMI 2.3.2.

Checking if there are duplicated records

```
df.duplicated().sum()
```

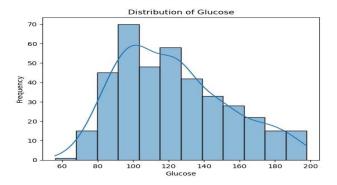

0

This 0 indicates that there are no duplicates.

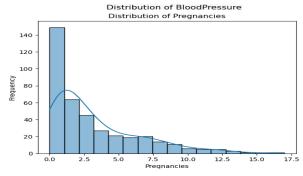

Having cleaned the data we can now proceed to analysis.....

- 2.4 Analyzing the Data
 - 2.4.1 Univariate analysis

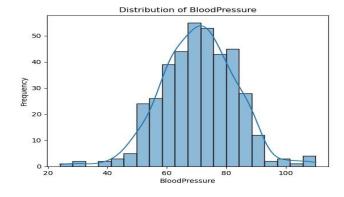

Visualization of each attribute to show its distribution. We start with histogram.

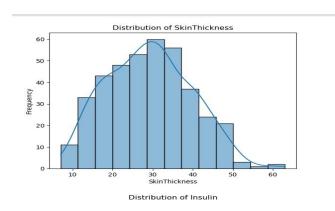

Glucose tend to be Fairly Symmetrical.

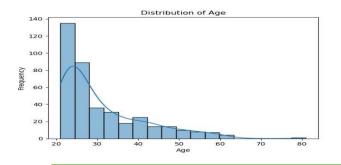

The distribution of pregnancies is right skewed with a higher Number Rate at 0-3 Pregnancies.

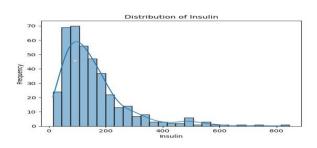

The distribution is symmetrical. With a curve at around 70 blood pressure

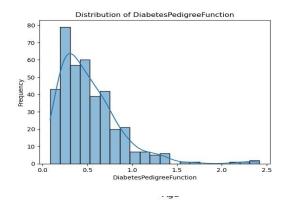

Distribution is symmetrical.

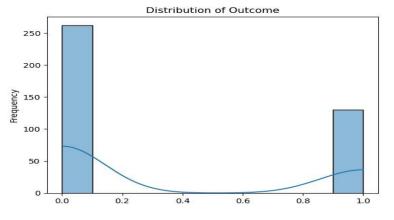

The distribution is left skewed.

Positively skewed

The distribution is right skewed with a great concentration 0.25

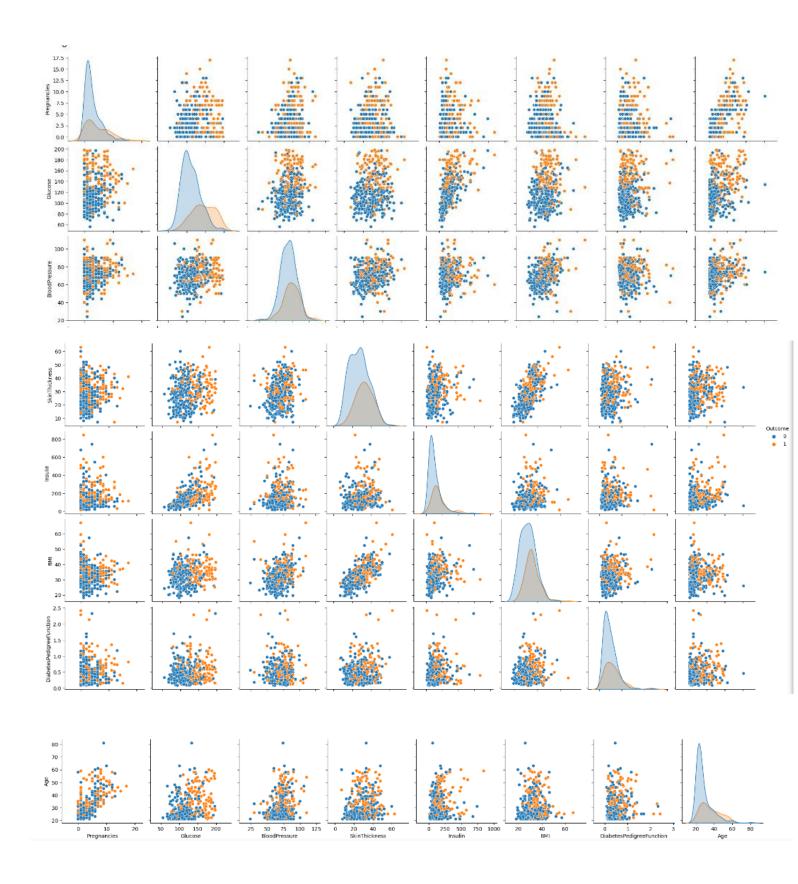

There exist two values for outcome. Those with no diabetic being more that with diabetic.

2.4.2 Bivariate Analysis

Plotting pairplots plots to show the relationship between two variables.

```
plt.figure(figsize=(20,10))
sns.pairplot(df,hue="Outcome")
```

Observations;

- There is no relationship between pregnancies and other variables. The Outcomes are evenly
 distributed for both the diabetic and non-diabetic. However, for the age variable, as the Age
 increases with increase in pregnancies the tendency of becoming diabetic rises.
- There is a very low relationship between glucose and other variables. Increase in glucose level increases the rate of getting diabetic and a decrease in levels of Glucose minimizes the risk.
- Glucose and other variables have similar relationship. Whereby with increase in glucose the level of becoming diabetic also increases.
- An increase in blood pressure with increase in glucose increases the risk of being diabetics.
- An increase in skin thickness with increase in glucose increases the risk of being diabetic and vice versa is true.
- Increase in diabetic pedigree with increase in BMI increases the risk of diabetic and vice versa is true.

2.4.3 Correlation analysis

```
##correllation
corr=df.corr(method="spearman")
corr
```

	Pregnancies	Glucose	BloodPressure	SkinThickness	Insulin	ВМІ	DiabetesPedigreeFunction	Age	Outcome
Pregnancies	1.000000	0.190481	0.152414	0.054759	0.123154	-0.065551	0.011713	0.633657	0.200234
Glucose	0.190481	1.000000	0.236609	0.215838	0.658958	0.199071	0.089346	0.350305	0.498729
BloodPressure	0.152414	0.236609	1.000000	0.250106	0.131639	0.317427	-0.020892	0.329244	0.198127
SkinThickness	0.054759	0.215838	0.250106	1.000000	0.241145	0.674393	0.093049	0.241507	0.260153
Insulin	0.123154	0.658958	0.131639	0.241145	1.000000	0.300906	0.131515	0.260747	0.375019
BMI	-0.065551	0.199071	0.317427	0.674393	0.300906	1.000000	0.096242	0.166963	0.267077
DiabetesPedigreeFunction	0.011713	0.089346	-0.020892	0.093049	0.131515	0.096242	1.000000	0.102984	0.198214
Age	0.633657	0.350305	0.329244	0.241507	0.260747	0.166963	0.102984	1.000000	0.397355
Outcome	0.200234	0.498729	0.198127	0.260153	0.375019	0.267077	0.198214	0.397355	1.000000

We see a great correlation between Age and pregnancies, Glucose and insulin, skinThickness and BMI.

There is very low relationship between DiabetesPedigreeFunction and all other variables.

2.4.3.1 Plotting a heat map to visualize the correlation

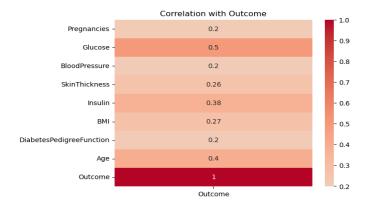

```
##heatmap
plt.figure(figsize=(10, 8)) # Adjust the size of the figure if needed
sns.heatmap(corr, annot=True, fmt=".2f", cmap="coolwarm", annot_kws={"size": 10})
plt.show()
```

The six variables with high correlation are the most efficient for model training.

Showing correlation between all variables our target variable (Outcome)

```
for column in df.columns:
    sns.heatmap(corr[['Outcome']], annot=True, cmap='coolwarm', center=0)
    plt.title('Correlation with Outcome')
    plt.show()
```

Observations;

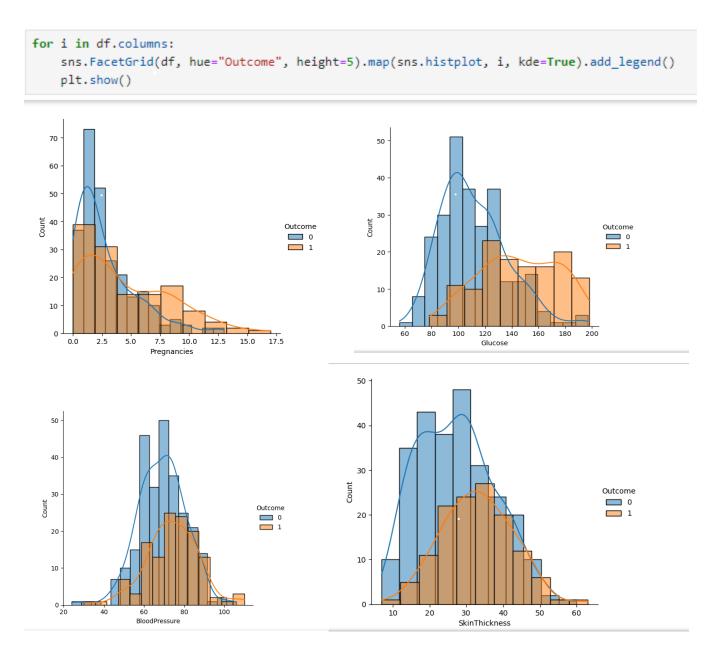

Looking at the values we see that all the valuables have great influence on the Outcome.

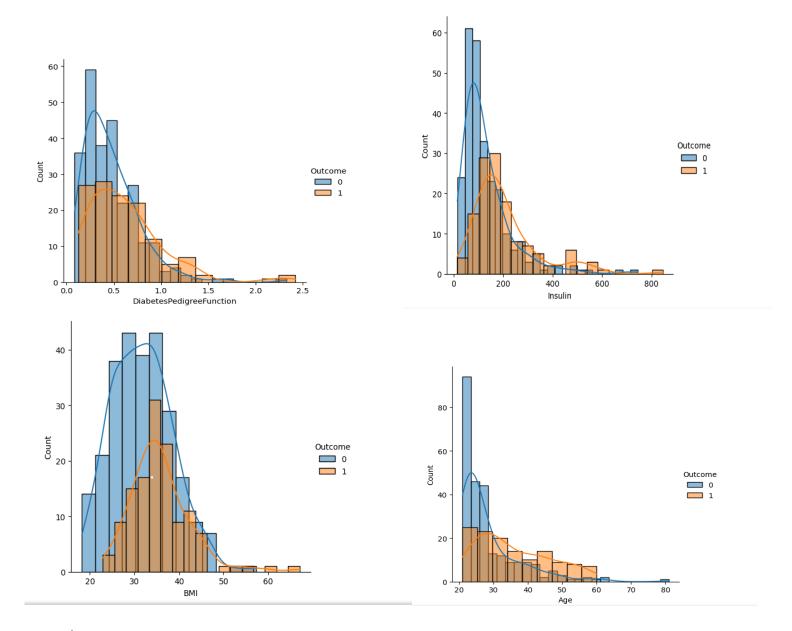

2.5 Univariate Analysis

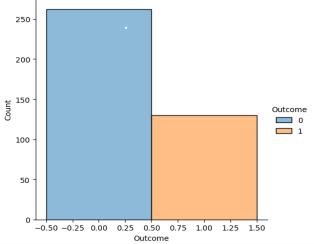

Univariate analysis focuses on studying the characteristics and distribution of a single variable independently, without considering its relationship with other variables.

2.5.1 Density plot/ distribution plot

We can use a simple graph to see how Glucose levels relate to outcomes, but it's clear that there's a considerable mix of results. We can apply the same method to other factors to find any consistent trends.

2.5.5.2 Splitting data frames based on Outcome

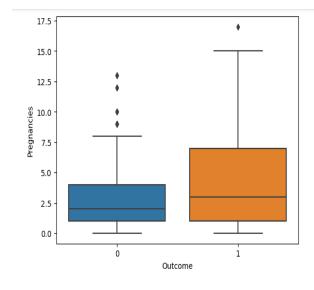

We split the data into two based on outcomes.

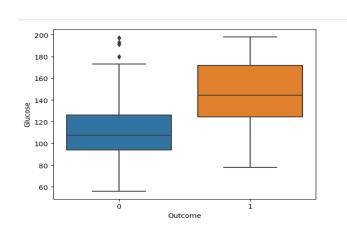

```
diabetes_yes=df.loc[df["Outcome"]==1]
diabetes_no=df.loc[df["Outcome"]==0]
```

Records identified as diabetic are assigned as diabetes_yes and Records identified as non-diabetic are assigned diabetes_no.

2.5.5.3 Box plots

```
for i in df.drop(columns="Outcome").columns:
    sns.boxplot(x="Outcome", y=i, data=df)
    plt.show()
```

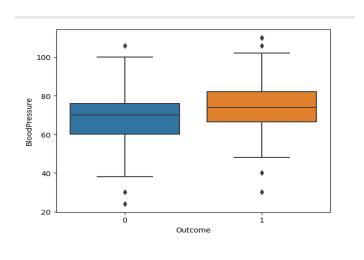

There are outlier for the Pregnancies variable.

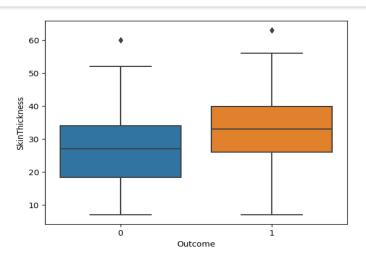

The median for the non-diabetic is lower than

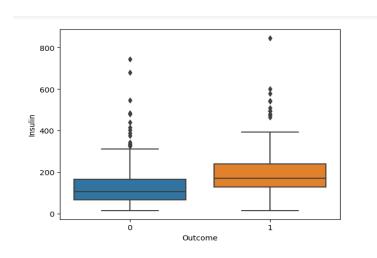

For the diabetic. The lower interquartile lies the

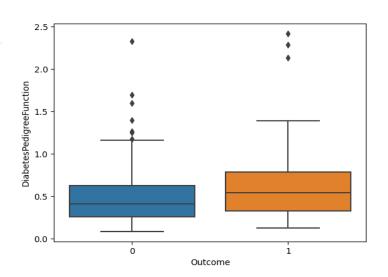

Same level at around 1 pregnancy.

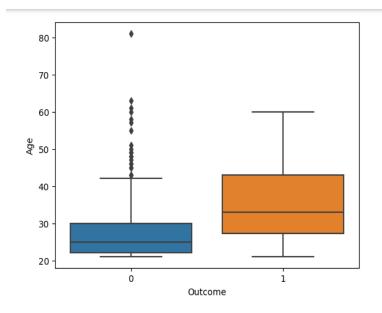

Glucose has outlier for the non-diabetic. The mean for the diabetic is greater that for the non diabetic

Observations;

•	There are outliers in all the features
